

Basic Workflow (using github):

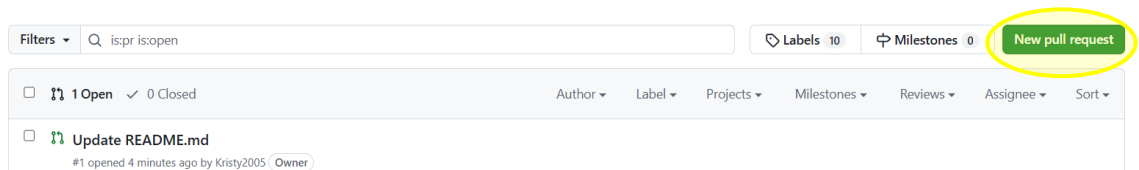

1. Pull most recent code from main branch

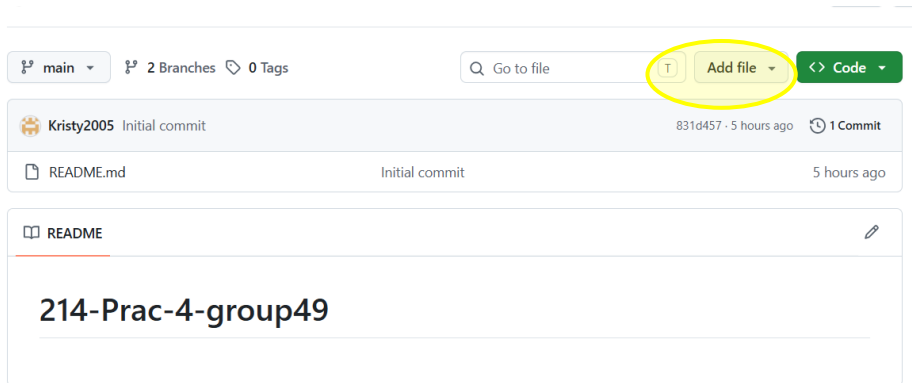

2. Edit the relevant code you want to on your device
3. Once code runs with no memory leaks or errors, make a pull request
 1. If changing an existing file, upload changes and commit here:

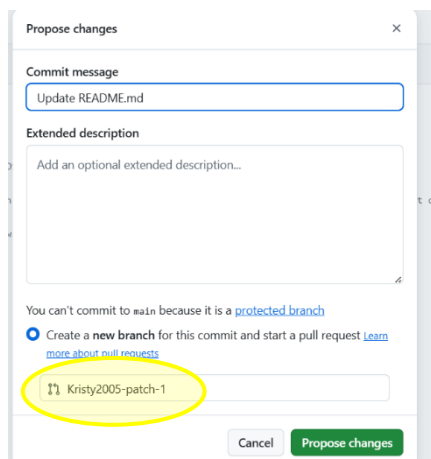

2. you can also just make a new pull request

3. Or just add the updated files here

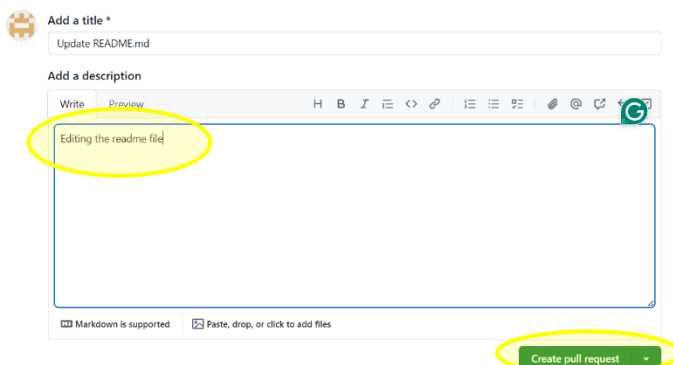

(I personally just add it from here from main, so that I create a new feature branch by default by the rule set. It won't add it directly to main, it will make a feature branch, and force you to make a merge request for others to approve before it merges directly to main)

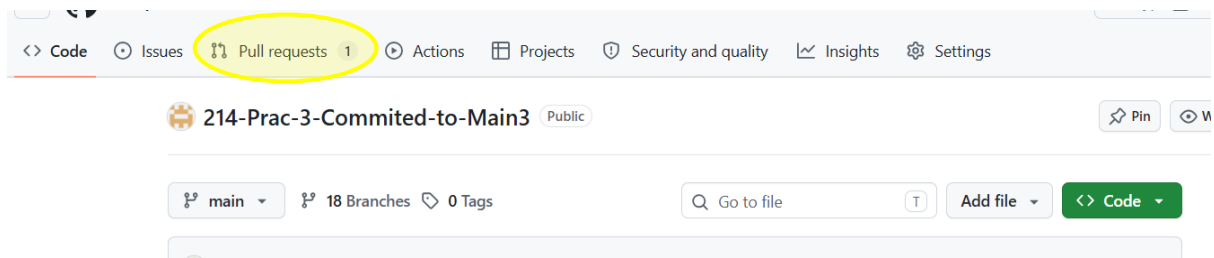

The yellow circle is the default feature branch

4. Write a description so we know what changes to look out for when reviewing, then create the pull request.

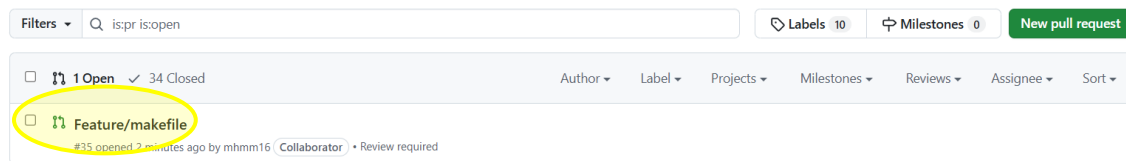

(once it's in the pull request tab, please message on whatsapp to tell us to go review it)

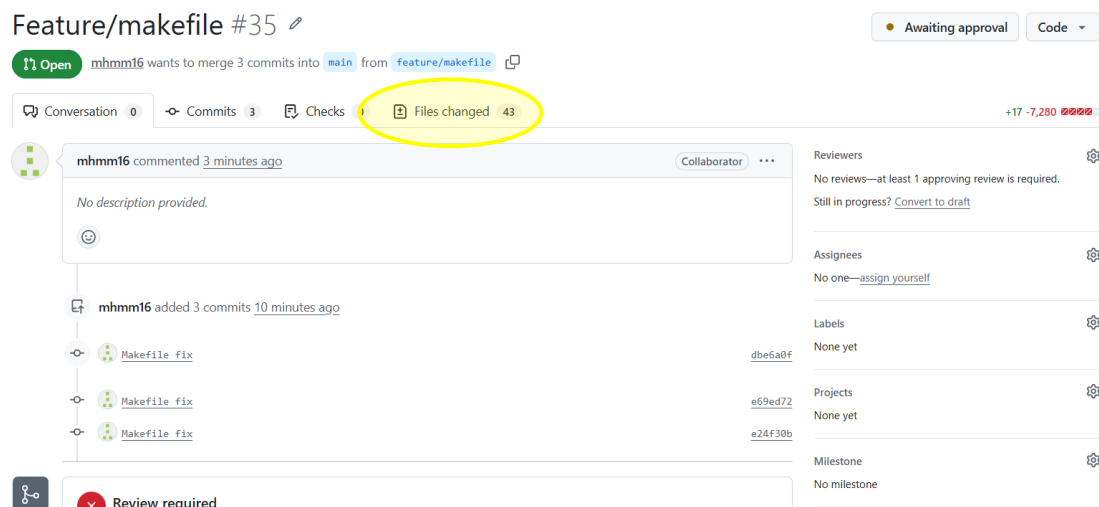

5.To review and approve a merge request, go to the pull request tab

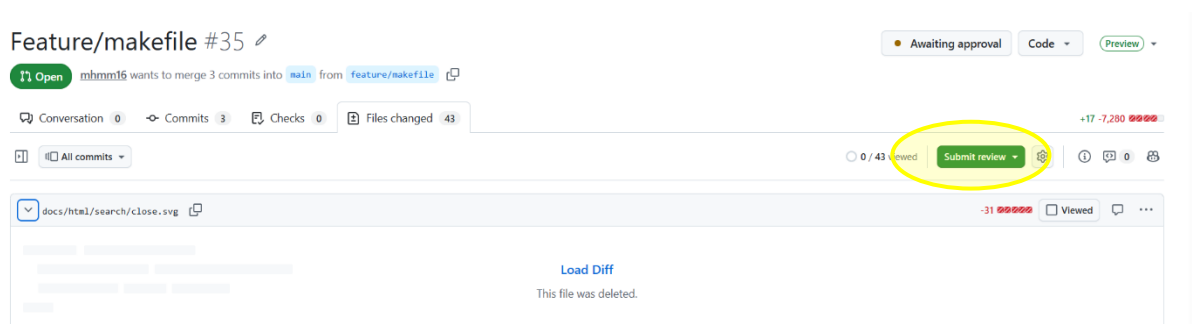

6.Always look at the earliest one to approve first, because we must be careful not to replace someones code with an outdated version

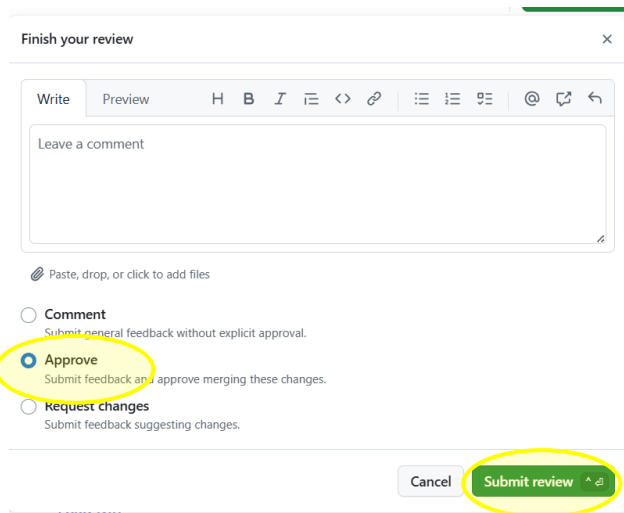

7.once opened, go to files changed, and review the changes carefully. You can also download the raw file to check if it runs, and is compatible to be extra sure

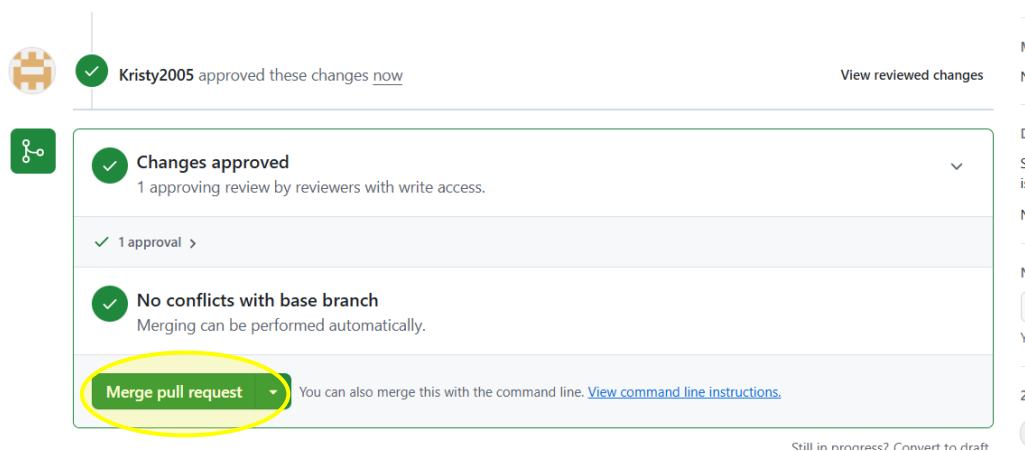

8.once you have checked the other persons pull request, go to submit review

9. you can write a comment on the code “ie. Code runs effieciently for Task 3” and approve. You don’t need to comment to submit, but its good practice.

10. Once you have pressed submit review, you can click on merge pull request. This merges the feature branch to main

11. its ask you to confirm then done. The file will appear in the main branch
